2. **Product description**

The PolarSpeed®-S (PolarSpeed® Shutter) is a liquid crystal (LC)-based optical shutter (variable filter) that controls the light transmittance by an externally applied drive voltage. Compared to conventional mechanical shutters, LC shutters are electro-optical; they contain no moving parts, are completely vibration-free, and have a small footprint.

The shutter consists of a polarization modulator in the form of two LC cells positioned between linear polarizers. Applying the drive voltage reorients the birefringent LC molecules, changing the phase retardation of light passing through the LC cell. This results in a change in transmittance of light passing through the full shutter structure. Analogue gray-scale operation between fully open and closed states is realized by voltage amplitude modulation, allowing the shutter to be used as a variable filter.

Based on LC-Tec’s patented PolarSpeed® technology, this dual-cell shutter offers unprecedented 30µs symmetrical switching times in both directions, closing as well as opening. The PolarSpeed® shutter is especially suitable for demanding high frame rate applications, such as time-multiplexed stereoscopic 3D, and is compatible with up to 540 FPS operation.

For demanding optical applications, the PolarSpeed®-S can also be supplied with an optical quality, high-efficiency AR cover glass laminated to both sides of the shutter. This configuration minimizes surface reflection, beam deviation, and wavefront aberration, and is especially recommended for imaging applications. The suffix -AR is then added to the model name.

4. **Custom designing**

Customers not finding their required shutter properties are advised that other FOS models are available and that further optimization and custom designing are possible, both in terms of electro-optical properties and mechanical dimensions (up to 14”x16” size).

---

2. Refer to drawing in section 10.5.
3. Reliability tests performed over a range of environmental conditions according to standard IEC 61747-5.
4. Dry, no condensation.
5. The specified values are valid for the 1x1 size and measured at room temperature (23°C ± 3°C).
6. Refers to unpolarized incident light, the corresponding value for linearly polarized light is significantly higher.
7. LC relaxation reset time required between switches.
8. As measured with \( f=60Hz, V_D=12V \) AC square drive waveform with transition slew rate of 3.5V/\( \mu \)s. Actual figures will vary with waveform slew rate, amplitude, frequency, and shutter size. Also see section 9.
8. **Typical values (PolarSpeed®-S @ room temperature and $V_D=24V$ unless other specified)**

8.1. **Open and closed state transmittance vs. wavelength**

8.2. **Transmittance vs. drive voltage amplitude (refers to cell 1, cell 2 @ V=0)**
8.3. Closing time at room temperature, normalized transmittance vs. time

8.4. Closing time vs. temperature

8.5. Opening time at room temperature, normalized transmittance vs. time
8.6. Opening time vs. temperature

8.7. Maximum frame rate vs. temperature
9. **Drive voltage and recommended controller**

In order to achieve rapid switching in both directions two LC cells are arranged in optical series in such a way that during one of the subframes the second cell compensates the first one to exhibit a combined property of not changing the state of polarization of normally incident light passing through them. This compensation principle holds for the field-off state of both cells, and is also valid if the same voltage level is applied to both cells as well as if the applied voltage is changed from one level to another and the LC material in the cells relaxes to the new voltage level.

The figure below illustrates the specific dual-cell drive waveforms that results in rapid switching in both directions. The same voltage amplitude should be applied to both cells. The duration $t_0$ to $t_1$ (and $t_3$ to $t_4$) must be longer than the LC response time ($100\mu$s recommended). The duration of $t_1$ to $t_2$ and $(t_4$ to $t_5$) is given by the desired frame rate, but must be longer than the LC relaxation time.

In order to prevent ion migration within the LC layer that might impair shutter performance and lifetime, it is recommended to ensure that there is no net DC bias present in the drive signal.

The LCC-230 (*LC-Tec Part number LCT-030*) is a flexible, full-featured liquid crystal controller specifically designed to drive all FOS, X-FOS, PolarSpeed®, and PolarView® models (but not the FSD, requiring high-voltage driving). The LCC-230 incorporates two independent LC channels, each with $30V_{\text{RMS}}$ of range and fully short-circuit protected. The controller is operated by the LCDriver2 application via a full-speed USB 2.0 compliant interface. LCDriver2 permits dynamic editing of programs up to 96 lines in length. Three trigger modes (internal, line, program) determine how program lines are executed. Up to nine programs may also be pre-stored on the LCC-230 for stand-alone operation. See user manual for further information.

**Note:** Customer-developed LC drive stages must be able to deliver at least the peak current of the specific FOS device to be driven. Output-stage ballast capacitors with a maximum ripple current rating at least three times the peak current is recommended.
10. Measurement methods and definitions

10.1. Transmittance, color, and contrast
The transmittance is defined as the luminous transmittance of collimated unpolarized light passing perpendicularly through the shutter according to:

\[
T = \frac{\int_{380}^{780} T(\lambda)D(\lambda)P(\lambda)d\lambda}{\int_{380}^{780} D(\lambda)P(\lambda)d\lambda}
\]

where \( T(\lambda) \) is the transmittance function of the shutter, \( D(\lambda) \) is the illuminant spectral distribution, and \( P(\lambda) \) is the photopic response of the human eye. All transmittance values specified are based on the standard illuminant CIE E (equal-energy for all wavelengths). The corresponding color is mathematically described using the color matching functions of the CIE 1931 Standard Colorimetric Observer, and is represented by a point in the \( u',v' \) chromaticity coordinate system.

The contrast is defined as the ratio of the transmittance of the open, non-compensating state to that of the closed, compensating state according to:

\[
C = \frac{T_{\text{open (non-compensating)}}}{T_{\text{closed (compensating)}}}
\]

Since the transmittance depends on applied drive voltage, also the contrast is a function of the voltage and usually increases with increasing amplitude.

10.2. Angular dependence
The transmittance is not only a function of light wavelength and applied drive voltage. Since the phase retardation induced by the LC cell also depends on the angle between the direction of light and the long axis of the LC molecules, the transmittance of the shutter can for a given angle of incidence be described by:

\[
T = T(\theta, \phi, \lambda, V_D)
\]

where \( \theta \) is the polar angle between the light exit direction and the normal vector to the surface, and \( \phi \) is the azimuth angle of the light exit direction as specified below.

The angular dependence of the transmittance or of the contrast between the open and closed states in diffuse light is often illustrated in a so-called polar plot as shown below. Iso-transmittance or iso-contrast lines describe the transmittance or contrast values at various angles. The center of the plot corresponds to light exiting perpendicularly from the shutter surface.
10.3. $T_{50}$ voltage
The $T_{50}$ voltage represents the point on the transmittance vs. applied drive voltage curve where the shutter is switched midway between closed and open states, i.e. the voltage that corresponds to a transmittance level (gray level) of 50% of the normalized open state transmittance.

10.4. Switching times
Two switching times are associated with the shutter. The time for closing the shutter, closing time (also called response time or $t_{\text{on}}$ time), is defined as the time it takes for the shutter to switch from 100% to 10% ($T_{100}$-$T_{10}$) of its static open transmittance after the drive voltage is applied to cell 2. The corresponding time for opening the shutter, opening time (also called response time or $t_{\text{on}}$ time), is defined as the time it takes for the shutter to switch from 0% to 90% ($T_{0}$-$T_{90}$) of its static open transmittance after the drive voltage is applied to cell 1.

PolarSpeed® technology enables rapid switching in both directions. The opening time as well as the closing time decrease with increasing drive voltage amplitude and increasing temperature. Also the maximum frame rate increases with increasing temperature. See section 9 for information about required drive signals.

10.5. Polarizer transmission axis
11. Mechanical dimensions

PolarSpeed®-S _ STANDARD SIZES

2x2_PolarSpeed®-S

D2_PolarSpeed®-S

1x1_PolarSpeed®-S

D1_PolarSpeed®-S

13x15_PolarSpeed®-S

7x8_PolarSpeed®-S

Refers to available standard sizes. Custom designing up to 14”x 16” size is offered.
12. **Electrical connection and wiring**

The desired waveforms should be applied to the shutter via the connectors present on the LC cells. Specific dual-cell waveforms are required as described in section 9. The larger shutter sizes, from 13x15 and up (13x15, 1x1, 2x2, D1, and D2), are supplied with contact pins as standard as illustrated in the mechanical dimensions drawings. The pin design is compatible with readily available 2.54mm pitch connectors (for example Molex Part Number 90123-0102). Customers can also solder wires to the pins, alternatively connect them directly to a dedicated printed circuit board (PCB) if desired.

The smaller 7x8 size is supplied with a flexible flat cable (FFC) as standard as illustrated in the mechanical dimensions drawings. The cable design is compatible with readily available FFC/FPC connectors (for example Molex Part Number 503480-0600, 52746-0671, and 52745-0697). Customers can also solder wires to the FFC.

Custom designed connector solutions, including variations of pins, FFC, and wires, can be provided upon request.
13. Handling precautions
The following provides recommendations for handling of this product.

LC shutter handling and cleaning precautions
- A protective film is supplied on both sides of the shutter and should be left in place until the shutter is required for operation.
- Even though the polarizers have a hard-coating on the outer surface, please guard against scratching, do not rub with abrasives.
- Keep the shutter surface clean. Do not touch without protective gloves.
- The -AR version has an optical quality, high-efficiency AR cover glass laminated to both sides of the shutter, please guard against scratching, do not rub with abrasives.
- Should the surface become contaminated, wipe lightly with a soft cloth moistened with solvent (isopropyl alcohol or ethyl alcohol) in order to clean the shutter surface.
- Do not wipe the shutter surface with dry or hard materials that may damage the surface. Do not use the following solvents for cleaning: water, aromatics, acetone or other ketone.
- Since this shutter contains glass substrates, avoid applying mechanical shock or pressure. Do not drop, bend, twist or press on the shutter.

Storage
- Avoid exposure to direct sunlight or high temperature and humidity. Recommended storage conditions: temperature range +5°C to +45°C with humidity <60%RH.
- Do not store the shutter near organic solvents or corrosive gases.
- Keep the shutter protected from vibration, shock, and pressure.

Operating precautions
- It is important to operate the shutter within the specified voltage limits; higher voltages may significantly reduce the lifetime of the shutter.
- The use of direct current drive (DC voltage) should be avoided since a reaction stimulated by such current significantly reduces the lifetime of the shutter.
- The switching speed of the shutter will be reduced at lower temperatures, and the shutter will show a dark color at higher temperatures. However, the shutter will revert to normal operation once the temperature conditions return to the range for normal operation.

Safety
- Should the shutter become damaged and the skin is exposed to liquid crystal material, it is recommended to immediately wash off the liquid crystal material using soap and water.
- If the liquid crystal material should come into contact with the eye, flush the eye using running water for at least five minutes. Seek medical advice.
